AI and Representation: A Study of a Rhetorical Context for Legitimacy

Lynette A. C. Hunter
School of English, University of Leeds, Leeds, UK

Abstract: Theoretical commentaries on AI often operate as a metadiscourse on the world in which science represents itself to a wider public. The sciences and humanities do the same of work but in different fields that encourage them to talk about their work differently: science refers to a natural world that does not talk back, and the humanities refer continually to a world with communicative people in it. This paper suggests that much AI commentary is misconceived because it models itself on the way that science represents itself, rather than on the a practice of science.

AI theorists have become increasingly worried about the lack of evaluation in AI, the lack of reflexivity, and the lack of contact with society. Frequently these writers turn to concepts such as knowledge to work through these worries. In doing so they are recognising the problem AI’s second-order representation of science and trying to deal with it. However, this recognition of a problem with the representations of science simply turns back to the legitimation crisis in Western politics where many commentators use science precisely as a ‘model’ for political institutions. They do so because science is one of the few areas of knowledge where the politicians are legitimate to use plausible methodology for representation that allows for arbi- trary designations of authority as well as parallel systems of different authority. However, plausible rejects any control on reflexivity, assumes an ethnocentric club culture and does not address social context.

It is in this sense that the problems of legitimation in political liberalism are similar to those of legitimation in sciences, both are rooted in their uses of representation. AI’s link with representation of science places it in the heart of this debate about legitimation. This paper suggests that AI does need to learn about reflexivity and that it might well do so by looking at the recent work on experimentation and representation by historians of science, and by looking at the debates about representation by historians of science, and by looking at the debates about representation within the humanities. However, reflexivity may not be enough. Devising a form of thumb for the appropriate halting of reflexivity is also needed to address social context.

Keywords: Artificial intelligence; Ethnocentricity; Legitimation; Rhetoric; Science (epistemology); Social context
1. Introduction

In the short history of AI it is evident that it has begun to explore a variety of techniques and methods, but it has yet to learn how to involve reflexivity in order to provide contexts for them. And although reflexivity is a step along the way considered methodology and processes of assessing social value, in rhetorical AI needs not only an understanding of ethos and pathos, the participant in the responsive context, but an awareness of stance which provides guidelines for how to use continual reflexivity in order to make decisions about necessary social action.

In 1991 a lucid and empowered essay by David Kirsh outlined a variety of approaches to AI, and took on the big issues of cognition, representation and learning. In the process of doing so he positions as a central concern, questions to do with how we come to agree to common grounds for representation, and charts the move by some AI researchers from axioms to plural perspectives. While the critique of logicist assumptions is welcome and in these hands sophisticated, the plurality of results does not address issues of social immediacy and action.

More and more commentators recognise the need in their talk about evaluation of how do we know when AI can be said to be valuable? More to the point, how do we know that value is not just success in fulfilling the internally constituted rules of self-defining worlds, but is rather an intersection with social needs that offers an opportunity for addressing them. Evaluation is pertinent to all areas of inquiry, but particular AI at the moment, because there are so few rules of thumb for the way in which deals with representation and touches upon reality.

Possibly because of its intimate relationship with modern science and its attention to method, AI has concentrated on finding techniques and plausible common grounds for its work. In rhetoric plausible argument works from opinion, and argument from basic assumptions held by a group of people. In contrast, probable argument first attempts to discuss commonly held ground, decides upon its appropriateness for the argument in question, and only then proceeds to argue from it. There has been a lot of commentary on the advantages and disadvantages of plausible argument, with most writers agreeing that the plausible is the root of deceit and manipulation. There is also a line that rejects rhetoric entirely and claims that since truth about certain things is absolute and can be known and articulated, basic assumptions do not need to be discussed; in other words the 'plausible' is not relevant to 'certain' things, defined, of course, by the individual and/or hegemonic group on behalf of others. Rhetoricians frequently concur that probable argument is the practical and helpful, but that plausible argument is often necessary because of constraints or the need for immediate action.

At least since Aristotle, science and more generally, ordered knowledge, has been described as an activity which need not engage in probable argument all the time. One of the reasons given for this is that within a field of knowledge, pec which are part of that field by definition have worked through the basic assumptions. They are pursuing that science only because they have entered a club, a culture v ground to which they have given prior assent. The problem, of course, is that activity of assent is soon forgotten for a variety of reasons (Gooding, 1989, p. 2) and the door is closed on the reassessments enabled by probable argument. Indeed the whole of intellectual pursui
which people behave as if they are working with ‘certainties’, or at the very least if there are basic assumptions that do not need to be questioned, that are independent of context and appropriateness.

Kirsh defines AI as based on the description of a consensual reality with adequate vocabulary for articulating concepts that underpin “the millions of things we know and that we assume everyone else knows”¹. But having been articulated description is rarely questioned. It is perhaps significant that the fields of inquiry recognised as impinging most directly on AI, from philosophy and linguistic theoretical computer science and cognitive science, are not those demanding sc immediacy. On the other hand inquiry in the humanities is seen to have retained and abiding interest in precisely what makes for appropriateness and attention to sc context.

If AI is to assess appropriateness, it has a specific problem because it is perceived as more relevant to the sciences than the arts and humanities. Assessing the common grounds for representation will have to push open the door to rhetoric that Aristotle pushed to, and will have to move the public debates of science from the plausible to the probable. The plausible can be accepted and even fun, for work of games that do not impinge on social relations of dominance and power. Where the social systems of scientific games become increasingly influential through various technologies and engineering, politics makes assessment essential. The first stage of assessment is to question, both what is appropriate to say and what necessary to say but difficult.

2. Rhetoric, Reflexivity and Stance

A rhetorical approach to the politics of representation that results when the arts humanities come to deal with computers and computing (Gardin, 1990), sets up discussion about the illusions of power offered by closed systems, and the problem of knowing when they have ceased to be helpful or whether it is even possible to open them up. This discussion is analogous to the much broader debate about political implications of communication that has been going on in Western European political philosophy for some time, as it has attempted to cope with the effects of sudden authorization in the early 20th century of new voices from the recently enfranchised population. Suddenly the whole process of how one finds and assesses common grounds, which had been worked out even in the post-medieval work terms of effective power politics for a small elite, was placed in the world of widely varied and huge public.

The problem of differentiating between the necessary and immediate agreement about appropriate common grounds (the probable), and habitual agreement about them (the plausible), has been problematised by the sheer size and number of more divergent and conflicting needs and desires. Both consensus argumentation directed to a decision about action in which all the discussants participate (Gadamer, 197 and corporate argumentation in favour of an action which will be taken on behalf the participants (Habermas, 1987), may lead to tacit agreement about adequate representation. The latter shift from corporate to totalitarian argument has been well-documented, but the elision from consensus to the self-enclosed cynicism of
nostalgia of the pluralist worlds of hyperliberal club culture has only recently l
to be described.\textsuperscript{3}

As this paper will suggest, the activity of modern science has much in cor
with club culture but is also working, significantly, in a representative mode t
completely different to that of the humanities. Furthermore, it is not surprisin
science has become a central motif in the discussions about ‘legitimation cris
the state, given that science is the one field where working with plausible arg
on opinion, as if it were certain, is expected and authorised by the represen
mode. Current descriptions refer to science working within the self-enclosed \of ‘paradigms’, either large-scale Kuhnian structures on the competing pluralit
post-modernism described by Lyotard (1979). If writers such as Gadame
Habermas proposed, in the 1970s and 1980s respectively, a return to probable arg
through assessed consensus discussion, or a return to corporate argumentati
universals (Habermas, 1987, p. 194), others, such as Rorty following an im
line in Althusser, argue that the distinction between the probable and the plausi
not relevant because we all do live in enclosed club cultures, therefore the pro
is always opinion: there is no need to distinguish between an appropriate ai
inappropriate ground, there is no need to assess social context.

My position here is this: that it is necessary to assess social context, to di
appropriateness, to attempt to distinguish the probable from the plausible. This
will argue that AI has been caught, for specific reasons, into duplicating club ci
when it could be precisely the place where science attempts a different represen

Reflexivity and How to Stop it

If AI is to take a stance on the activities of science and technology that it appe
describe, it needs first to become self-conscious about its own techniques ai
strategies. AI is about finding ways to represent the activities of human intellig
both how we represent the world to ourselves (knowledge representation) and
we deal with that representation, respond to it, interact with it (expert systems
it and so on. Representation is a complex area, and it is not the intention he
limit it to even sophisticated versions of visual verisimilitude or structural congru
Rather, I would like to place AI within the carefully detailed debates to whic
long history of representation in the arts and humanities has led. This is to undo
the rhetorical work of representing which involves not only \textit{technique} and de
but discussion of \textit{strategy}, and most importantly an assessment of \textit{stance}. It is w
stance that the dilemma about evaluation in humanities computing can be addre
And it is questions about evaluation in AI that urgently need to be answered b
it can sensibly position itself with regard to technology and power. This discu
will focus on issues of self-consciousness, strategy and reflexivity.

A consideration of strategy has to include a sense of where the speaker or a
or writer is placed within the description. In traditional rhetoric, ‘ethos’ im
taking up a particular role or perspective with relation to the audience, whose resj
was in turn cast as ‘pathos’. Ethos implies a fairly stable set of conventions :
the relation between the speaker and the discussion; for example, written genre
the letter or report, assume certain strategic relations once they are realised; v
not usually expect a report to be a lyric poem. Generally, within rhetorical study there is growing contemporary concern with an increasingly varied audience subtly elaborated questions about the effect of the speaker on the discussion literary ‘deconstruction’ and the ‘reflexivity’ of the social sciences, there has an extension of ethos to include an on-going assessment of how participation affects the event.

If we look reflexively or self-consciously at how our participation in both event and its representation affects that event or representation, questions are raised about various parts of our knowledge and perception that are adequately articulate. From difficult questions, such as ‘why do you feel depressed to apparently simple ones such as ‘why do you like cheese?’, we often find we and other media inadequate to the representation of what we feel or know. Reflexivity is on-going and continuous precisely because that knowledge cannot satisfactc be communicated, and this indicates a further problem: reflexivity is a useful but its continuous activity does not encourage positions to be taken from wl decisions can be made and specific actions carried out.

The problem is how and where to halt reflexivity. On-going questionin; frequently halted at points where articulation appears inadequate. We stop and atte some kind of communicative context for a practice that resists discussion. But if attempt is made merely in response to a resistance, then reflexivity simply st again and moves on to the next (arbitrary) difficulty. Used in this manner, the becomes intensely private. It works within a system of absolute/arbitrary dichotom which define much of the social action that can be taken by the individual as priv and science is an intensely private activity.

Articulation and its pair, ‘tacit’ knowledge, lies at the heart of the debates at legitimation in science: Is tacit knowledge unarticulated because it is impossible articulate, because people have not yet tried to articulate it, because it has becc habit, because it is blind prejudice, or because it is ‘true’ and does not need articulati This range of questions sits parallel with the range of AI approaches listed by Ki (1991), from distributed AI to moboticists to connectionists to Soar to logici Without social context it is impossible to distinguish. With private use of reflexiv there is no sense in assessing which of the many difficulties it is necessary to d with, nor is there any sense of placing an attempt at articulation before a public, purposes of evaluation (how appropriate is it in addressing social needs?) or criti (is it appropriate at all?). This is why strategy, whether stable ethos or on-go reflexivity and deconstruction, needs stance that places it in a social context.

This version of the ‘legitimation crisis’ which stresses the problem of distinguish the habitual from the appropriate public and social common grounds for representati is related to the problem in cognivist rational analytics of the distinction betw prejudice, which is accepted blindly without question, and the axiom or explici stated rule (Adorno, 1982). Yet the two versions are not entirely congruent becau the cognivist dilemma does not deal with the difference or distinction betwe regulative and constitutive rules, rule-following and rule-performing, that mal the debate about habitual/appropriate analogous to the further problem of how distinguish self-evident from working knowledge (Feyerabend, 1975) or ta knowledge (Polanyi, 1967), and indeed how to distinguish these two, habitual appropriate, from each other. These issues are directly relevant to theorising ab
evaluation in AI, which has moved inexorably toward concepts of practical knowledge and performance. This has happened largely because the aims of AI to represent expertise, cannot be satisfied by equilvalating knowledge to information, or expertise to regulative rule-following. But in order to understand the necessary concepts, AI must learn how to become self-conscious about techniques and methods.

Evaluation for the arts and humanities in the post-medieval period has focused on reflexive questioning of common grounds or topics as they are conveyed by representation, even though much humanistic activity does not do this. Philosophers and what is temporarily called theory, has become the recognised place where we attempt to find new common grounds and try out their appropriateness, as we assess the continued appropriateness of others. Theory is not prescriptive but constructive and descriptive. The whole point of theory is that it addresses areas of knowledge or perception in our lives that we find difficult to talk about (phronesis) (Bergendahl, 1990, p. 186; Gadamer, 1976, pp. xxv and 120) and them in contact with the craft of communicating (technē), so that we can try to articulate adequate to the context of our day to day lives, that will enable us to make decisions about events and to act.

Appropriate action is the broader significance of the world ‘proper’ as in search for a ‘proper meaning’ (Hunter, 1989, pp. 169–70). In the humanities, this action is sharply noticeable in the theoretical debates about gender and race, in which people work within a dominant discourse, a dominant set of common ground and strategies, that ignores and even represses their different knowledge, have shifted away from opposing the repression to attempting to find ways of articulating repressed knowledge. The debates about ‘class’ are particularly difficult to refer to terms not of opposition but of unarticulated knowledge. Each area needs to refer to certain norms of communication for granted in its theory, or literally, it will appear to be talking nonsense. Articulating what is known but not yet articulated is a process involving the speaker, the medium and the audience. If the audience no longer has a common ground of communication at all, neither will it be about to be of significance or sense of the text. At the same time, each area is self-conscious of assessing common grounds and attempting new ones, and that reflexivity is unitary because each one has different guidelines about where to halt and so the value of its representations.

Modern science differs from the arts and humanities in that rather than having human beings or other human-created texts as its referent, it claims the natural world and the constructions that people have made out of it. This difference resulted in a profound difference in the way that the sciences and human communicate to any public audience. For the ‘hard’ sciences, knowledge is the natural work (phronesis); it is known from doing the experimentation (technē) and practising scientists are fairly continually reflective about this engagement with reality by way of assessing the grounds of their scientific method (Gooding, 1992). But while the referent participates in this, it does not talk to them. Furthermore, communication about this knowledge to a public is second-order articulation about the first-order experiment, and therefore, finds it easy to lose normative and conventional grounds for expression rather than reflexively assess purpose.
about the world not about a changing communicative society; the communicative already at one remove from the real activity.

The attempt at methodology which has come to define modern science in Western world since the 17th century, can be seen as an attempt to provide precise guidelines that halt the reflexivity that public discussion entails (Shapin, 1980). But this attempt to halt reflexivity is not in aid of evaluating the grounds appropriate to social action. In science, the stress on methodology and on technique of experimentation, can be seen as an attempt to question the unsatisfactory area of plausible grounds of scientific argumentation, by taking science out of the social demands of communication. The desire of the Royal Society for a pure cognitivist language can be recast, not in terms of a concern for the objectivity of language in its own sake so that it can refer to the world precisely and accurately, but for objectivity of language so that it can represent the experiment exactly. Further, the new science needed a plain language without its own textuality because many Protestant reformers of that early time it wanted, and still often wants, to with a natural-world reality that can fill out or complete the emptiness of world they stand by themselves, as if words were bags to put the reality known into experiment into. This denial of textuality is exacerbated from another directive of technology begins to use science to make commercial profit from the 18th to century. What permits technology to commodify or make money out of science ability to represent science mechanically (Henderson, 1986) as a fixed method of producing ‘true’ products.

It is a self-defeating agenda: science defines language as inadequate to representation of the experience of reality, and suitable only for the report in methodology. Hence the public understanding of science is restricted to the cliched version of scientific prose as a parody of technical rhetorical structure of propositio, inventio, narratio, conclusio; and scientific language as rational, analytic and cognitivist (Bazerman, 1987). By closing the door onto society, in an attempt to get rid of the merely plausible, science only succeeded in restricting to phony demonstration its communication about what it was effectively concerned (Gooding et al., 1989), and in producing a set of representations of its methodology that did not take account of common grounds – which is exactly where the plausibility comes from: unassessed habitual agreement.

One of the commentators to have emerged from the debate over the legitimacy of science, whose work is pertinent because it appears to applaud and authorise the plausibility of community habits of interaction, is Richard Rorty. Rorty rejects textuality or grounds that representation is inadequately referential (1991a, p. 8), and in this duplicity the rejection of rhetorical stance enacted by science when it accepts that the language cannot convey the action of experimentation. He notes that this inadequacy of representation raises insoluble questions about the absolute and the relative, wishes to replace it with ‘habits of acting’ and interaction with a ‘neighbourhood’ (p. 10). It is the case that if a stance is adopted that wants manmade control over aspects of language that model it as a mirror of the world, then these dichotomies emerge; indeed most of 20th century psychoanalysis engages with this and other consequences of the stance of fantasy which technically it is (Hunter, 1984). But there are other choices of rhetorical stance such as allegory or dialogism, or even the various poetic stances that have been built by people who have agreed to look at
appropriateness of the structures of representation rather than dismiss the prob-
that result from belatedly recognising that language is not exact.

What is curious about Rorty is that instead of choosing another stance, he
with this impoverished notion of representation and because of its impoverish-
chooses to ignore it altogether. His arguments suggest that if representation is droq
then metaphysics and epistemology can be replaced by politics, which is to as:
that metaphysics and epistemology have never had anything to do with pol
whereas if rhetorical stance and social context is retained then so is the pol:
dimension. In effect, in dropping representation, analysis leading to political a
is evaded; for Rorty phronesis never needs to be articulated – indeed articulati
textualising is seen as a reductive and ultimately intolerant act (1991a, p. 25). How
as the rejection of rhetoric by science underlines (Hunter, 1984), drop
representation, avoiding textualty, simply disguises the fact that all commun:
involve power relations. Discourses that pretend otherwise, like science, bec
‘the most potent instrument(s)’ of power for persuasion in our society (Ca
1989, p. 161). The reason that Rorty’s position is curious is that the comfort
elision into competency that marks exclusive club cultures and their excess, scien
technology to liberal/authoritarian regimes (Bauman, 1989, p. 12; R
1991a, p. 44), is something those societies frequently attempt to resist, yet w
Rorty offers as a desirable end; and desirable is just what it is. Elsewher
characterises ‘habits of acting’ as the private narcissism and public pragmatist
210) that make up the solidarity of club culture. It is however, only the ‘leisure’
civilisation’ of bourgeois liberalism (p. 25) that permits the desires of pri
narcissism to remain ‘tolerant’ rather than brutal.8

Bourgeois liberalism assumes a large measure of individual autonomy, but it
effect, dependent on an institutionalised state structure that creates conditio
private autonomy within a highly regulated public practice. Rorty suggests
‘civilised’ culture is autonomous from the institutional regulations of police
bureaucrats (p. 26), whereas it can only behave as if it were so by refusin
become aware of the institutional structure. It is the need for the doublethin
simultaneously acknowledging state structure and then forgetting it in order to op
as a private pragmatist, that underlines how deeply embedded is this approach i
structures it seeks to evade, and which rather surprisingly, aligns it with versio
Althusserian state apparatuses,9 although it owes its primary allegiance to Feyerab
The doublethink is here called ‘ethnocentrism’, and is contrasted in an ar
specifically on science, with rationalism and its “criteria for success [which laid
down in advance” (p. 36); but, in effect, ethnocentrism is simply what hap
rationalism when it forgets the need to look at common grounds, treats the
given and does away with textualty. While the reflexivity of scientific experi
is its strength, its rejection of the textualty of communication has left it to t
increasingly enclosed worlds, small circles of private knowledge exchanged by m
of a specialist jargon. These worlds are often valuable but frequently bee
alarmingly narrow and reductive and only continue to exist because of instituti
support (p. 39).

In contrast, for the arts and humanities, communication in a medium is a or-
activity. Because they are concerned with human referents which engag
the activity of knowing, communication itself becomes the site of knowledge. W
is not to say that there is a necessary connection with society: the further away the arts move from public discourse the closer they come to duplicating, in, for example, the 19th century avant-garde, the small circles of private knowledge typical of sciences (Williams, 1987). But both the arts and the humanities find common ground in the activity of their human texts, in the mimetic performing, repeating, imitating of these texts (Cave, 1986). This is one of the reasons why it is so important for humanities users of computing to understand the constraints of the system of a software text (Goranzon, 1990; Miall, 1990), let alone hardware: they need not know not only what the rules of the software will permit, but how to perform textuality within the large critical context (Hunter, 1990). It is in this latter act that they can reach evaluations, assessments of the knowledge that the interactive software text and literary text has enabled.

Because the communication of their knowledge is part of that knowledge humanities have also traditionally claimed to focus on reflexive social questic of methodology at the same time as using it, although they have not always can do it out. When they do, they help to maintain the socially immediate criteria by which we know how the common grounds of agreement and representation are being assessed and encourage attempts to be clear about the relations of convention and domination that are involved and about the relation between articulated and unarticulated knowledge. Such evaluation of stance helps to make clear whether we are see new common grounds, rationally extending old ones, breaking up existing common grounds, breaking through existing common grounds, offering different ones, replacing old ones, assessing old ones, using old ones self-evidently or fictionally or artificially and so on.10

AI and the Representation of Scientific Methodology

For AI, both articulated and unarticulated knowledge are related to the activity of mimic human intelligence (Goranzon, 1990). Yet because AI conventionally provides a theoretical space for working out the representation of science and technology, most AI currently deals in representation as if it were only cognit (Wagman, 1991). It is as if it were taking the limited representations of method in science and technology for the first-order actions (phronesis) necessary to represent (techne) in order to articulate knowledge. Hence it is concerned not so much with the textuality which encourages repetition of an activity that locates (mimesis), and assesses the appropriateness of common grounds for all kinds of knowledge perception, but with a stable set of common grounds that evades the implication of their plausible basis and seeks only to represent experimentation or at worst, to the ‘success’ or ‘failure’ of that representation. The frustration with this approach is becoming more evident in AI writing itself, with some writers claiming to work without representation at all because it is self-delusory, or to shift it into plur:

The problems here are specific. First, that if assessment is not self-conscious, then old common grounds will be taken as self-evident, yet second, that constant experimentation is an arbitrary gamesmanship that lets one win or lose but does not offer new common grounds for action. Since the communication of science and the commercial acti of technology (Miles et al., 1988; Molina, 1989) depends upon treating the self-evide
as axiomatic and the unarticulated as irrelevant knowledge, AI is restricted to the process of looking for rationally acceptable topoi (Hunter, 1991b) – models, di analogues, frames (Greene, 1986) – in order to represent. Because of the restrict of cognitivism, Hubert Dreyfus defines a ‘cognitivist’ as a rationalist with a com (Dreyfus, 1988), AI tends to find these representations in regulative rule-based systems.  

This tendency to reproduce the patterns of intensely private theory, and to v. within the structures of artificially closed worlds, is what ties AI to fantasy, to the rhetorical stance of technology and industrial capitalism (Johnson, 1989; Hui 1991b) which attempts to create isolated worlds that deny larger social and political interaction (Ennals, 1991, p. 41). Yet it is precisely there that assessing appropriateness of common grounds is not only most difficult but also necessary. The concepts most frequently discussed by people involved in theorising AI intimately tied to the techniques for building self-defining worlds. The central devices are: algorithmic knowledge (Penrose, 1989), predicative knowledge (Janik, 1991), digital representation, propositional descriptions (Lytot, 1979), regulative r (Wittgenstein, 1953; Polanyi, 1967), determinist structures. Each is a part of a dot that presents its other face, which is frequently offered as the reflexive alternative mathematical knowledge, tacit knowledge, analogical representation, narrat description, constitutive rules, relativism. What this essay will go on to do is discuss the uselessness of these doublets to AI in an attempt to contextualise its methods become reflexive about its practices. The discussion here will argue not that determinate and relativist doublet can be ignored, or that it should be evaded (Rc 1991a), but that AI has failed to pursue reflexivity because it was misled into taking the communication of scientific method for the practice, and has as a result, avoids the complexities of representation, particularly of constructing new grounds unarticulated knowledge and perception. The immediate questions then become: How can representation become self-conscious or reflexive? What is unarticulated knowledge? What can it be for AI? Can it become articulated, and if so, how? How do we halt reflexivity in social appropriateness?

**AI and the Articulation of Working or Tacit Knowledge**

As the limitations of rationalist, cognitivist approaches have become insistent has crept toward the social by introducing contextual factors. The pre-determinate common-grounds of the methodologies may satisfy attempts to know fact, inform and data, but they fail to ask about knowledge of practice which demands spec context (Winograd and Flores, 1986; Ennals and Gardin, 1990; Ennals, 1991). That is a striking problem here: if practice, or working knowledge of how somethin done, is often silent and inarticulable, how can AI represent it? One of the anxiety about working with models provided by AI derives from this awareness that beca the models give the illusion of completeness, people working with them will fold the unarticulated practical knowledge that comes from working with the actual wo (Cooley, 197X; Goranson, 1990). But if the representations work by encourag reflexivity about their limits and exclusions then the user gets access to analog ways of representing practical knowledge, that are at the same time, ways participating in that knowledge (Ennals, 1991, p. 71). One result of this latter approc
is the recognition that what people who work with computers need above training (Boden, 1989, p. 166), not just in information representation, but in a set of skills developed in the arts and humanities for representing a much wide of knowledge.

Dreyfus and Janik

If AI has crept toward context, many theorists of philosophy and epistemology explicitly raised (social) questions about AI and practical knowledge. So w practical or tacit knowledge? The point of agreement among many differen that tacit knowledge is knowledge by the expert, the knowledge of the expertis is learned in practice. In an attempt to illustrate why AI models often beat begi but rarely measure up to experts, Dreyfus outlines a “phenomenology of s behaviour” that moves from novice, to advanced beginner, to competent proficiency, to expertise. In the process he describes a gradual internalisati heuristic procedures so that the proficient performer is able to understand a prc with immediacy and then “must deliberate about how best” to act (Dreyfus, 19 105); however, the expert has internalised both understanding and action, so tl [sic] ‘does not solve problems. He does what in his experience, has normally w and, naturally, it normally works (p. 106). What is missing from this account i attempt to describe how the ‘intuitive’ expertise differs from cognitive heur nor does Dreyfus attempt a representation of expertise. The remainder of the illust he offers ascribes the roots of cognitivism in Western epistemology to Plato, v is ironic, since Plato attempts one of the most enduring representativ non-cognitivist expertise in his accounts of writing, medicine and gardening i Phaedrus (Hunter, 1984).

It is precisely this problem with the representation or articulation of exp that is central to the future of AI. Richard Ennals has called it the ‘bottleneck’ development; and Alan Janik, who has been a guiding hand to many comment interested in the implications of practice for AI, makes the possibility of articl the focal point in his definition of the tacit knowledge of expertise. Janik distingu between tacit knowledge that can be articulated but happens not to be, such as secrets or recipes (Janik, 1987, p. 55), and tacit knowledge which cannot be artic even if we wanted to do so. Here he offers the two examples of “certain non-v sensory experience and procedure involved in following a specific rule” (p. 55) elucidation of both kinds of tacit knowledge for labour management and understanding the “limits of the possible” in actual working contexts, is clear helpful. It provides a way of talking about ‘quality’ within the economics of produ (p. 61), as well as the basis for a critique of both Habermas and Gadamer. j describes the irrelevancy of universalist/generalising principles of legitimatio labour-relations working within structures of domination; but he also insists recognition of the limits of any particular community or set of actual condit This is essential if philosophers are to halt the continual reflexiveness typical o cynicism and nostalgia of postmodernism.

However, there is a problem with the example of “impossible to articu knowledge. The case on non-visual sensory experience that is offered is the ‘s of coffee’ (p. 56): because we do not have an articulation adequate to describing;
smell so that someone unfamiliar with it could recognise it, we have to suscet metaphors and analogies. What Janik does not go on to consider is what hap then.\textsuperscript{12} In common with agreements about visual representation, there are freqe nts agreements made by particular groups of people about the adequacy of an articu late representing other sensory experience. People not part of a group will have asn o problem recognising visual representation, as they will with representation of other sensory experience. To this extent, the visual is not distinguishable from o senses, although it often appears to be so because technological development global media have educated a considerable part of the world’s population to spe and sophisticated agreements about it. And, to the same extent as the visual, other senses are open to education in representation. Wittgenstein uses the s example, the aroma of coffee, to discuss the way that we experience a mis description (1953, p. 610), but he is far less definite about the im/possibilit finding a verbal articulation for it.

More interesting, but also more problematic, is Janik’s description of l constitutive rule-following resists articulation, and this is an argument also infor by Wittgenstein. Janik notes:

Rule following activity entails the kind of knowledge that is only acquired through repetition or practice, terminates in creative activity as we learn that we have to guess how to continue to follow the exa we have been given and, ultimately, as we learn to invent new ways of carrying on...In short it analogical rather than a digital activity...Moreover, if constitutive rules were known before their applic we could never learn to apply rules without more rules...(p. 578).

What is not considered here is the way that constitutive rules tend to beco regulative with repetition, with time and with certain social contexts (Conner 1989). The way in which social context effectively brings together both regula and constitutive, is underlined by Wittgenstein (1953, pt. 179e) when he refers to ‘tacit presuppositions’ on which any analogical ‘language-game’ rests. Differentl Austin directs the latter part of How to do things with Words (1962) at distinguish be-tween what he calls the constative (descriptive) and the performative (constructi as part of a larger attempt to distinguish between locutionary (correspondence \ the facts), and illocutionary, utterances. He notes that while the constative may r to be ‘right’ in the sense of being ‘true’ to “your knowledge of the facts”, l constative and performative may raise questions about ‘right’ in the sense of whe “this was the proper thing to say” (p. 145). Social context, or “the total speech at the total speech situation is the only actual phenomenon” (p. 148) which may eluci the distinction.

Social context is brought together with time and repetition in the consistent coherent history of the process of topical or analogical reasoning documented by arts and humanities (Hunter, 1991a). A topos or a common ground will be hamme out into language among a number of people attempting to find a place, literally ground upon which to discuss and decide issues. Janik himself uses the ph “seeing where we are” (p. 57). Once the topos is ‘in place’ and has provide helpful ground for learning about issues, the sense of its specific appropriat elides into generalisation. The related procedure of the ‘cliche’, or ‘cliquer’ f the clicking of type into a printer’s composing stick which allows for mult repetitions of the same thing, is exactly to repeat an appropriate analogy so o that it becomes regulative, self-evident and banal. At the same time, repetition l
the foregrounded artificiality of the analogy or ‘canonised example’ or ‘mod pattern’ (Janik, 1990, p. 50) that is representing practical knowledge, and the an becomes an accepted convention for that knowledge.

The articulation of practice will always be under historical and social pres: hence the articulations underpinning regulative rules will become inappropriat new common grounds, genres, canonical models and topoi will encourage necessitate new articulations. Whether the ‘need’ is answered is often depende financial and economic strictures. Janik hints at the importance of history and necessity in his criticism of Hubert Dreyfus as a ‘phenomenologist’ who doe distinguish between constitutive and regulative rule-following. Here Janik that regulative rules are “only possible on the basis of the former [constit rules” (1987, p. 48), but like Dreyfus he does not expand on the historical pr: by which the one representation can lead to the other.

Wittgenstein

Wittgenstein’s Philosophical Investigations and much of his later writing is prec concerned with a study of how we can represent “what is not the case” (1953, p which may account for the considerable number of commentators on pract tacit knowledge who turn to his work. Wittgenstein defines ‘philosophy’ mut: the humanities define ‘theory’, as discovery and description (pp. 47–48) of happens when normal, prescriptive rules do not work, when we get ‘tangled u the rules of the language game (p. 50). Just as teaching and learning need t: way of example and practice (pp. 63–64) rather than by propositions, so must lang in providing practical knowledge of reality, not limit itself to conceptual/cog representation. The language game is not an explanation but the “primary t: (p. 167). It must provide models as ‘comparative’ not dogmatic (p. 51); it understand the need for ‘appropriate’ words (p. 54). Common grounds are not ‘g simply because they make events more likely (the plausible), but because they an experiential ‘influence on the event’, they are part of it, they make it ‘r probable’ (p. 136).

Underlying Wittgenstein’s investigations is a careful critique of the practic cognitive and behavioural psychology contemporaneous with his writing. Freque the writer distinguishes between human ‘sciences’ and natural sciences on the gro that study of the former depends not upon measurement, calculation, instru: concepts, but upon the external sensory reactions of the subject (p. 151). An ends the investigations explicitly stating that through experimental method approaches that psychology makes to behaviour are a ‘conceptual confusion’ results in ‘barrenness’. This statement derives from the lengthy section (ii.xi) discusses the difference between seeing and ‘seeing as’, and that also provides J with a basis for distinguishing constitutive from regulative behaviour in term analogical from digital structure. Evaluation and judgement arise not from ex: rules but from the imitation of a practice by which we learn what to see (J: 1987, pp. 52–53). Tilghman (1990) uses this distinction to pursue question articulation and to define ‘seeing as’ as a practical knowing that is “usually ability to use the appropriate language and/or make appropriate comparisons”. Wittgenstein leaves us with is an uneasy indication that the socially ‘proper’
‘appropriate’ slide under pressures of time, use and history, into nominalisation. As he notes in the *Blue and Brown Books*, analogies can outstay their appropriate and become misleading (Hunter, 1989)

**Polanyi**

The focus on Wittgenstein and away from Michael Polanyi, who is often conside as the writer who opened up a wider discussion of the topic of tacit knowledge, ostensibly because Polanyi is considered ‘vague’ or even ‘mystical’.

But this apprehension derives in part from Polanyi’s stress on modern science rather than the and humanities, which means that he is not immediately concerned with the appropriate representation for communicating to a wide public, but with the appropriate experin which allows the individual to articulate physical reality. In other words he is concen with a different referent for the unarticulated tacit knowledge, and with a differe relationship to the audience. Since AI is a field of knowledge concerned \( \triangledown \) representation, Wittgenstein is highly relevant. However, AI gains much of its imp directly from scientific discourse, and often takes that discourse as a first-o representation of the knowledge of modern science with the result that it b: much of its articulation on regulative rules. Hence Polanyi’s careful study of difficulties of finding a representation for scientific experiment is also highly relev

In *The Tacit Dimension* (1967) Polanyi talks about scientific discovery as be guided by the sense of a presence of a hidden reality which discovery ‘termin and satisfies’. In doing so, “it claims to make contact with reality” (p. 24). Wha: interesting is that Polanyi’s sense is congruent with Wittgenstein’s on philoso that discovery is a series of hunches that are recognised as problems in the ‘perfo ance’ or physical practice of the experiment, by the experimenter/scientist. I sense of the scientist being reflexive by looking for problems rather than solutio and of science as performance rather that objective inquiry, forms the basis Lyotard’s discussion of science 20 years later, as the central activity of the postmoc condition. But Polanyi carefully notes the long history of this activity. He : outlines the problems that this reflexiveness inevitably meets because it lacks c connection with the social that a concern with the textuality of representation ensur

**Doublethink of Postmodern Pluralism: Arbitrary and Absolute or, Private and Systematic**

Lack of effective social mediation leaves the scientist grasping after private tru often called beauty,\(^{14}\) or the enormous satisfaction and pleasure of the system coherence of ideology. The isolated scientist can never know whether the discov or experimental practice is private truth about actuality, or has in effect, sudden made sense of a pre-existing system of epistemology. In other words, the scien can never answer the question of whether the inarticulate tacit knowledge has been (partially) articulated or whether the experiment has just got around to articula something that no one else had yet bothered with. Any private pursuit of truth end with this dilemma about the arbitrary or the absolute. Postmodernism enga in the doublethink so well described by George Orwell: of the arbitrary as absol or the absolute as arbitrary.
There have been attempts to rescue the ‘discovery’ of science by reloca-
firmly away from the cognitivist ‘algorithms’ of computing, into the ‘beau-
‘mystery’ of mathematics. Penrose (1989) attempts this restatement of classic truth and beauty, in order to point out the delusions of the ‘strong AI’ claim ‘the information content’ of individuals “can be translated...intact” (p. 26), t.
is adequate “for the description of brains and minds” (p. 402). Penrose unde-
the view that computing is algorithmic, following rules mindlessly, and incapable of.
evaluation, judgement of truth, or artistic appraisal; and this is an appro-
which he has been taken to task (e.g. Sloman, 1992). Here the emphasis is rat-
the private and egocentric grounds for the representation involved in his de
do of creative mathematics. He claims that the “evaluation of an algorithm can
conscious awareness” (p. 447), because the consciousness of mathematical is a matter of instantaneous ‘seeing’ that involves ‘inspiration, insight, and origin
the “strong conviction of the validity of a flash of inspiration...is very closely up with its aesthetic qualities” (p. 421). It is suggested that a mathematical is not information but a discovery akin to Plato’s ‘remembering’ – that the n-
matical concept “is, in a sense already present in the mind” (p. 429). It is an abs-
The reference to Plato and memory is significant because remembering w
‘already present’ is with Penrose narcissistically still limited to the isolated indiv
and does not take on the rather more active sense of re-membering, rebuild-
body, that occurs when the individual comes into contact with society that i
offered by Plato. The narcissistic image is the other face of the psychoanal-
vocabulary that recasts beauty as the nostalgic recognition of the self in the syn-
ystem of ideology where truth is a designed, interconnected network, and is w
with the cynical recognition of the difference of the self from the symbolic syst-
Significantly, both narcissism and cynicism depend upon the private individual
empowered with respect to the institutional structures of the public world. Postm-
 plurality is never challenged by itself, only by the different communities t
cludes and which may not be tolerant of its naive arrogance.\textsuperscript{16}

Penrose tries to distinguish the individual discovery of the ‘already pre-
fixed truth, from the sense of the brain ‘observing itself’ whenever a new perce-
emerges that is offered by systematic coherence. However, the two are the alter-
sides of the relativist and the deterministic, the private revolution and the tota-
system, neither of which acknowledge the difficulty of dealing with the real, \
cannot be approached without social interaction. Furthermore, once either app-
begins to question its own methodology, it cannot cease because there is no ser-
material/social need that can appropriately interrupt and focus on action (D
1989, p. 82; Rorty, 1991a, p. 39). What often happens instead is that the den-
for commodification and capitalism intervene, turning the scientist or science-
fame or technology. Both fame and technology claim to satisfy desire by closin-
circle of knowledge, so they immediately turn the constitutive rules of perform-
into regulative games in which the rules may be completed (Frude, 1989, p.
This is the precise way that commodification offers the seductions of power to
speaker and audience. Plato equates it with paying money for love (not sex).

Polanyi attempts to differentiate between this relativist/determinist double-
and science’s apprehended contact with the ‘real’, by way of the disturbance th-
discovery causes, saying that discoveries are ‘most real’ when they manifest thems
in the future in the largest range of indeterminate results (1967, p. 24). But Pola
also realises that the difficulty of distinguishing, in the elation of discovery, betw
the joy of an appropriate articulation for tacit knowledge and the ‘termination
satisfaction’ of power either individual or systematic, is the condition c
self-validating world of knowledge isolated from society. He adds that the scien
can utter “no…more than a responsible commitment” (p. 78) to the truth, and i
the universal claims of science are not determinist but of “universal intent” (p. 7

In his conclusion Polanyi notes that because the heuristic field of science is
stable but problematic, the scientific community must be spontaneously establis
by self-coordination’ (p. 92) or it will lead to a fragmented society “adrift, irresponsi
selfish, apparently chaotic”, where each scientist is responsible only to their c
small specialisation. These comments neatly describe the effects of postmodern
which Rorty would like to celebrate in the name of bourgeois liberalism; which Gada
tries to harness into self-coordination while failing to address the dilemma
distinguishing between plausible and probable grounds (between prejudices : tradi
ons), which Lyotard leaves adrift in the melancholy fragments of cynicism: nossalga: the mirror of Baudrillard’s ‘simulacrum’, and which Habermas wo
apparently like to address by reintroducing enlightenment ideals.

If tacit knowledge for science is knowledge of the reality of the physical wo
for the arts and humanities its is knowledge about the world of human interact
Any common grounds are shared with other human beings as the basis for all ty
of social action. Any attempt at new common grounds for unarticulated knowledge
must involve other human beings. For the arts and humanities the sense of sudde
sharing a new common ground with other human beings is part of the knowle
being articulated. The articulation and the making public are the same thing, altho
it could sensibly be argued that the social sciences stress a reality about hun
beings that is described in the repetition of appropriate representations, and
critical sciences/arts stress the contact with reality that is learned by repeating
performed moves in processes of imitation as if they were our own. In both stres
there has been a traditional focus on providing contexts for representations, rat
than delineating methodologies, although the ‘scientistan’ drive of the humanitie
the 20th century has been to take on methodology enthusiastically. While th
approaches have opened up the variety of ways in which we study and underst
other human beings, the methodology has frequently been used as an end in its
falling into the same trap as AI of taking the methodologies themselves as
reality to be represented. This has derailed much work from questions of reflexiven
into similar consolations of power offered by the commodities of fame and of
technology of criticism, with the result that the power has been left without appropri
context. It is this that has led the arts and humanities into ahistorical postmoderni
and generated what has come to be known as the ‘legitimate crisis’ in all discipli
of Western study.

Gadamer, Habermas, Lyotard, and more recently Rorty, offer versions of
same crisis, stemming from the same doublethink of the private and systematic,
arbitrary and the absolute. Gadamer does not deal with the problem of the ‘comm
ground as ideological because he chooses to work from the human animal out (19
pp. 110–111), as if biological necessity will inevitably be more significant th
ideological. He provides private reasons for reflexively finding and critiquing comm
grounds but not overthrowing them because implicitly he doesn’t believe or ever get outside them: there is no discussion of the pressure of contradiction, need to maintain common ground for taking decisive actions, of the prole competing common grounds, and the problem of not wanting to or not being a critique the commons ground characterised as a ‘false consensus’. He disting between ‘good’ and ‘socially successful’ argument (1987, p. 194), on the be whether the argument is questioned and defended or merely influential. How this offer of reflexive questioning as the way to distinguishing is not enough ‘influential’ argument may be challenged and then defended, while a ‘good; arg may have to change with social context. His distinction can in the end or maintained by calling on ‘universals’. Lyotard simply gets rid of the tern nec and universal, leaving the crisis of legitimation with the incessant reflexiveness; game that shuttles back and forth between the isolated private world and the syste or universal.

What is interesting about Lyotard’s reductiveness is that it underlines the c issue of evaluation: how to account for, assess, and act on, perceived contact or knowledge of, the real. There is no room for practical or tacit knowlec Lyotard’s version of ‘paralogy’, plurality of worlds. This is primarily because is no belief in a contact with the ‘real’. All representation operates within paral structures of private or systematic worlds. A recent version of this account pre replicates Lyotard’s rhetoric. In a paper analysing the ‘hard’ representation of sc by sociologists of science criticising ‘hard’ representation of nature, Steven Wc maps out three stages in sociology (1991, p. 44). The first is ‘instrumental second ‘interpretivist’ and the third, ‘reflexive’. The tripartite categories re approximate the divisions in rhetoric between technique, strategy or ethos, and s However, what rhetorical study emphasises is that while consciousness of s encourages reflexivity, it is not automatically something to be proud of, as Wc would have it. Reflexivity does insist on placing the ‘object’ (knowledge, scie; person) within the analyst’s own social forces, but the concept of stance add this is not a unitary activity: there are different ends and values involved in socia the context for an object. The problem is not just ‘to become reflexive’ but to d at which point it is appropriate to halt reflexivity in order to take decision effect social policy.

Here is can be appropriate to refer to the story of Pygmalion. The continu reflexive mind, endlessly deconstructive and sceptical, is implicitly utopian, sear without end for the ideal: that Pygmalion will be able to make Galatea articula reality perfectly. Yet Pygmalion needed the gods to start and to stop his articul To ignore the gods of biology, or any other universal, does not suddenly legit Pygmalion’s activities by conferring authority on him alone. Indeed, it merely ren the current rules of thumb about reality, and leaves Pygmalion playing arb games with Galatea within a self-enclosed monomaniac world.

3. AI and Representation

One reason that theorists/philosophers such as Gadamer and Habermas hang biological necessities and universals, is that they perceive the need for social ac
The whole process of articulating tacit knowledge is at the root of the liberal ethos of modern science, as it is for the humanities. What goes on in the articulation of tacit knowledge is the making public of the ways in which, or the points at which we have decided to halt reflexivity and take action. In any scientific approach partly because the communication of experimental work is already at one remove from the actual, and partly because of its methodological emphasis, the moment the knowledge derived through practice is articulated it appears to make claims about fixed truth. But what it is in effect doing is making claims on reality, and then intervening in it and changing it. Looking at how knowledge is made public provide guides to finding the 'appropriate' places to halt reflexivity.

The process of making public any claims on reality does not, for scient approaches, occur in the medium that the science works. But science still need public discourse. Hence, the burden of proof and repetition to involve other people in the contact with the real. Articulation of any working knowledge only happen as a result of common practice, otherwise there would be no one to recognise appropriate common grounds. Science specifically, works in small communities where 'comm practice' is the first mode of proof (Goody, 1989). The articulation puts that practice into a representation so that it can then be learned by a wider public, but all too often for reasons previously outlined, the articulation uses strategies that aim for 'truth'. Curiously, this mimics the particular politics of authoritarianism that are in the 20th century in response to the massive number of newly enfranchised people. The stance is an extension of fantasy that aims to satisfy representation by providing it with the self-validating terms of tautological structures. It frequently fails: results in force when presented to an audience which does not accept or does understand, its basic assumptions — as all those who have attempted to assess something from technical instructions will know. But science need not communicate this way. The knowledge it is about may be learned in quite different ways depend upon the articulation and particularly upon the stance. AI could be a helpful place to develop and assess more interesting approaches to scientific articulation and effects it has on scientific practice.

The array of dyads offered by commentators on AI and representation — constitutive regulative; mathematical/algorithmic; tacit/predicative and systematic; analogic digital; narrative/propositional, etc. — marks each first term as typical of the moments of elation where we think we touch reality. Strictly speaking, the dyads are different in kind. The constitutive or tacit knowledge of working practice is articulated mathematical, analogical, narrative representations, that may become algorithmic digital or propositional, and lead to regulative and predicative/systematic rules. However, there is no necessity for the elision from say analogical to digital, rather there is varying historical and social pressure. For example, if you live in a society with poorly developed practices for reading analogy into the large number of figures of which metaphor, metonymy, simile, allegory and so on, are but few, then analogy will slip swiftly into digital analogue. Different articulations affect practice in differing ways dependent on this pressure.

Once articulated, practical knowledge need not be merely related to a rule-bot system, because the text of articulation can permit the repetition of the performative practice or work that insisted on the articulation in the first place. However, at the same time as it makes it possible, articulated practical knowledge does inhibit
articulation of other practices. Some way of representing will be closed off if others will be opened up, so it becomes necessary to be reflexive about representation, to understand what our position is with respect to it, and how we participating in it, not so that we can engage in the incessant shuttle between private and the systematic (whether universal, ethnocentric or ideological), but that we can connect the articulated with the unarticulated and take a step to evaluating appropriateness.

To answer the questions of how much and where we are participating in representation, and what any articulation makes it difficult to say, we have to add the common grounds in the practice of that representation. Nearly all the comments on AI and society, whether or not they are concerned with tacit knowledge, discuss these questions of representations. The point in each case is to underline the need for constitutive practice, the first term in which each dyad of representational concern, not always followed up, is the need for reflexiveness that is initial step to constitutive practice. But constitutive practice involves an understudy of rhetorical stance which brings together the strategies of reflexiveness with the own critique of articulation; it brings together strategy and the material; it focusses precisely on the elision from constitutive to regulative and asks us to be clear about where to stop reflexiveness and take action.

The stance of AI has predominantly been based on the self-enclosed rhetoric of scientific communication. It moves inexorably around the structures of tautologies making that scientific methodology has elaborated, taking common ground axiomatic, as ‘agreement’, as ‘best fit’, as oppositional, as satisfactory, as unneurotic, and in this way raises peculiarly acutely the problems inherent in fantasy. The strategic fantasy as elaborated above is a way of dealing with unarticulated knowledge and social context, by treating all common grounds as systematic, yet choosy simultaneously to forget that strategy. Once the system has been defined, it satisfies any desire articulated within its common grounds. It can offer continual repetition of that satisfaction, it becomes addictive and the compulsive addiction of computer worlds is well-documented.

A recognition of this self-deluding procedure leads R. Brooks to try to complicate the need for representation in AI. He concludes that:

> When we examine very simple level intelligence we find that explicit representations and models of the world simply get in the way. It turns out to be better to use the world as its own model. (1991, p. 14)

What this reveals is that he takes ‘representation’ to be explicit and so of course finds it inadequate. Furthermore, using the world’s own models necessarily involves articulation of another representation. As he proceeds, Brooks appears to be becoming aware of this. He becomes insistently upon ‘traditional’ representation being the of the problem, and he turns elsewhere inventing in his notion of mbotics interest in new possibilities for AI. But as Kish’s commentary indicates, these have their own implicit representations (Kish, 1991b, pp. 161-184). Any evasion of representational concerns on the grounds that it is inadequate to the world is tautological because it is based on the concept of a linguistic adequacy which fails by definition. Kirsh points out that the idea of an inadequacy of axiomatic knowledge is also bound up in an essential basis on egocentricity; the denial of a public and social space (1991a, p. 21). These concerns parallel the broader ethnocentricity of Rorty, with his similar evasion
inadequate representation. And Brooks’ comments that he is not interested in the significance of the implications of his work, indicates a similar evasion of scientific concern.

The kind of satisfying repetition enabled by chosen or evaded tautological wc is quite different from the repetition enabled by the constitutive practic performance, because the common grounds of performance can never be defined within a fixed system. This realisation forms the centre of W. Clancey’s monograph Model construction operators (1992), about which he comments:

I realised that many confusions about representation could be resolved if we see them as alter perspectives on a single ‘virtual’ formal system. I realised that representation and reasoning problems were commonly viewed as different could be related by a shift in visualization. (p. 193)

Yet Clancey’s commentary on the way his approaches have developed, also: exactly parallels the shift in scientific concerns with representation from the plurality of postmodern design and its attendant problems. Some researchers turning to alternative ways of agreeing upon grounds for definition and upon gro for reference (Birnbaum, 1991; Kirsh 1991a, b; Smith, 1991). Rather than r directly into the plural versions of postmodern representation which, as commentators on representation in science have recognised, are still quite separate from society, perhaps AI could consider using the concepts of rhetorical st present in the humanities to pursue alternative ways of agreeing upon the gro for the representation its articulates.

Were AI able to investigate the constitutive rules of topical and analogical reason it might be able to offer science a mode of proof and repetition that reintroduce phronesis of science into its representation, reintroduces the probable and insistently the textuality of public communication. But if AI is to duplicate in virtual re the repetition of satisfaction that is the representation of science (by technolog mechanical reality, then it will place itself within the story of Frankenstein. U Pygmalion’s Galatea, Frankenstein’s creation is manmade with naive arrogance takes the second-order representation of science and makes it literally real; technics is born and there are no gods to get rid of it. It is helpful to remember that Pygmal is a myth by man for men, underlining a belief in their own god-like actions, v Frankenstein and the monster are part of a myth written by a woman looking man’s world, and providing a devastating critique of the literalising of fantasy.

The Contribution of Tacit Knowledge to Innovation

Jacqueline Senker
Science Policy Research Unit, University of Sussex, Brighton, UK

Abstract: Tacit knowledge is widely acknowledged to be an important component of innovation but such recognition is rarely accompanied by more detailed explanations about the nature of tacit knowledge, why such knowledge is significant, how it becomes codified or whether there may be limits to codification. This paper attempts to fill some of the gaps, drawing on a study of university/industry links in three emerging technologies. It concludes that tacit knowledge, which can only be transmitted through personal interaction, will continue to play an important role in innovation. This derives from a variety of reasons, but most significant are the complexity of systems and the emergence of new technologies.

Key words: Tacit knowledge; Innovation; Automation; Biotechnology; Advanced computing

Introduction

Studies of innovation, technology transfer and technology diffusion identify knowledge as an important component of innovation (e.g. Dosi, 1988; Roser 1976, 1982). None of these discussions provide a satisfactory definition of knowledge or give a detailed, systematic account of its role in technological innovation. Nor do they provide guidance on how its importance may differ according to the industrial sector or technology being studied or how firms acquire it.

This paper is an attempt to begin to fill some of these gaps. It will discuss methods developed by firms to capture tacit knowledge of a scientific and technological nature which is generated both within the company and that arising in external sources. It will also identify the company activities where tacit knowledge makes an important contribution to innovation and consider the processes by which knowledge becomes codified.

Much of the material arises from a recent study of university/industry linkages in three emerging technologies – biotechnology, advanced engineering ceramic processing – which investigated all the knowledge flows used by companies in the course of innovation (Senker & Faulkner, 1992). Results from this study will be presented after proposing a working definition for tacit knowledge and revising its role in the innovation process.
